Implication for health policy/practice/research/medical education:
Almost one out of 10 people suffers a childhood urinary tract infection (UTI). The prevalence of UTI in girls is about 1.5 times higher than that of boys. Therefore, gender is a risk factor for childhood UTI and girls are more prone to UTI compared to boys.

Introduction:
In a urinary tract infection (UTI), one or more parts of the urinary system, such as the ureter, kidney, or bladder, are infected (1). UTI is the second most common bacterial disease in children (after upper respiratory tract infections) and the most common bacterial infection that affects humans (2). The global prevalence of pediatric UTI is about 2%-20% (3).

In infected children, a UTI manifests with nonspecific symptoms, which causes confusion in diagnosis. Thus, high prevalence of UTIs in children without diagnosis and lack of proper treatment is a cause of clinical and general concern. Abdominal pain/suprapubic pain, vomiting, and fever along with chills are common symptoms of upper and lower UTIs that usually appear only after the age of 5 years (4). Internationally known definitions refer...
to the calendar age in specifying the boundary between childhood and adulthood, which often refers to the age of 18 as childhood. Therefore, the age range studied in our meta-analysis study was 0 to 18 years old. In this definition, childhood is divided into three categories, including early childhood (<6 years), middle childhood (6-12 years), old childhood (12-18 years) (5). Due to high prevalence of UTIs in childhood and its dangerous complications, as well as the different results of published studies in this area, it is necessary to conduct a systematic review and meta-analysis.

**Methods**

**Study protocol**
The present study is a systematic review and meta-analysis examining the prevalence of UTIs in childhood.

**Study population**
The study population was all under 18 years old and no gender or race restrictions were imposed on them.

**Primary outcome**
The main outcome of this study was prevalence of UTIs in childhood.

**Secondary outcome**
The secondary outcomes include prevalence of UTIs in girls and boys, and prevalence organisms of UTIs in childhood.

**Search strategy**
In this systematic review, the international databases of PubMed, Scopus, Web of Science, Cochrane, and the Google Scholar search engine were searched. The articles up to 15.02.2021 were included and the search process was performed using the following keywords: “Urinary Tract Infections, UTI, Children, Prevalence” using their English equivalents mapped in the MeSH (Medical Subject Headings). In addition, their combinations were searched in English language databases using the “AND” and “OR” operators. Search strategy in PubMed: (((Urinary Tract Infections [Title/Abstract]) OR (UTI [Title/Abstract])) AND (Children [Title/Abstract])) AND (Prevalence [Title/Abstract]).

**Inclusion criteria**
All studies that examined the prevalence of UTIs in childhood (<18 year) were included in the study.

**Exclusion criteria**
Studies with non-randomized sample selection, studies that examined the prevalence of recurrence of UTIs, studies with incomplete information, studies whose full text was not available, studies which were not of the desired quality, Studies examining the prevalence of risk factors for UTIs.

**Qualitative evaluation**
The researchers examined the quality of articles using the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) checklist (6), a well-known international standard checklist for qualitative evaluation of articles. This checklist consists of 22 different sections and covers different parts of a report including sampling, variable measurement, statistical analysis, confounding modifications, validity, and reliability of used tools and study objectives. The score range for this checklist is between 0 and 44, and articles scoring <15.5 were excluded from the study.

**Extracting data**
To minimize bias in reports and errors in data collection, two researchers extracted data from studies independently. These researchers entered the extracted data into a checklist consisting of researcher's name, year, sample size, number of girls and boys, prevalence of UTIs in childhood, prevalence of organisms of UTIs in childhood. Another researcher examined the extracted data to resolve any discrepancies. In case that in one of the initial articles or studies, the required data were not reported, an email was sent to the corresponding author inquiring him/her to send them.

**Statistical analysis**
In this study, the variances of each study were calculated using the binomial distribution formula. The heterogeneity evaluation was done by Q-Cochran test and I² index. Considering the high heterogeneity of the studies, a random effects model was used to estimate the point prevalence with 95% CI. The data were analyzed in STATA software 14 and a P value <0.05 was considered significant. Meta-regression was used to investigate the relationship between the prevalence of UTIs in childhood with year of publication of the study.

**Results**

**Literature research**
In the early stages, 515 articles were found from the above-mentioned databases, among which 235 overlapping studies were excluded by reviewing the study titles. The abstracts of the remaining 280 articles were reviewed, and out of this number, 179 articles were removed according to the exclusion criteria. Out of the remaining 101 articles, 65 articles were excluded due to their incomplete information or lack of full text. Finally, 36 articles reached the quality evaluation stage, all of which had good quality and entered the meta-analysis process (Figure 1).

**Characteristics of studies**
A summary of the information extracted from the reviewed articles is given in Table 1. In 36 studies conducted on 78212 samples and published between 2000 and 2021, the prevalence of UTIs in children...
Urinary tract infection (under 18 years) was reported at 15% (95% CI: 13%, 17%) (Figure 2).

Analysis of subgroups
The prevalence of UTIs was 16% in girls (95% CI: 12%, 19%) and 10% in boys (95% CI: 7%, 13%). Regarding organisms of childhood UTIs, the lowest and highest prevalence was related to *Citrobacter* with 2% (95% CI: 1%, 3%) and *Escherichia coli* with 58% (95% CI: 46%, 69%), respectively. The list of countries where only one study was conducted is not included in Table 2.

Additional analysis
Figure 3 shows that the prevalence of UTIs in childhood has increased during the years 2000 to 2021 and this relationship is statistically significant ($P=0.012$).

Discussion
The prevalence of childhood UTIs in the present study was estimated at 15%. The results of the study by Hasegan et al. on people under the age of 18 also showed that the prevalence of UTIs in a population of 15389 was 9% (9). In a study by Bulte et al (18), in a sample of 6079 people aged below five years, the prevalence of UTI was reported at 5%. In a study Carried out by Wu CT on 5470 children aged below three years, the prevalence of UTIs was reported at 11.3% (15). The prevalence of childhood UTIs in the above-mentioned studies is lower than the prevalence of UTIs in the present meta-analysis (15%). In the study by Filler et al (31) in Canada on 3422 people with a mean age of 9.6 years, its prevalence was reported to be 16.1%. One of the reasons for this difference in its prevalence may be related to difference in sample size and studied age group.

Regarding childhood UTIs, the prevalence of the studied organisms varied from 2% to 58%. Consistent with the results of the present study, the most common organism was *Escherichia coli* in the studies conducted by Kumar et al (7) in India, Alhares et al (8) in Iraq, Mohammed et al

</table>
In the present meta-analysis, we concluded that the prevalence of UTIs was 16% in girls and 10% in boys. The results of the study by Alhares et al in Iraq showed that the prevalence of UTIs in 101 children aged 1.5 to 10 years was 43.6% (14.9% for girls and 28.9% for boys). In Nigeria, Anigilaje et al (21) evaluated 52 children aged 2 to 15 years. The prevalence of UTI in girls 15.4% and in boys 23% were. In both of above-mentioned studies, the prevalence of UTI in girls was lower than that in boys, which is inconsistent with the results of the present meta-analysis. In another study by Msaki et al (25) in Tanzania on 231 children aged below 5 years, the prevalence of UTIs was 26.9% in girls and 12.4% in boys which is consistent with the results of our research.

**Conclusion**

Almost one out of 10 people suffers a childhood UTI. The prevalence of UTIs in girls is about 1.5 times higher than that of boys. Therefore, gender is a risk factor for childhood UTI and girls are more prone to UTIs compared to boys. Since the prevalence of UTI in developed countries is lower than in developing countries, it is possible that the prevalence of UTI in children is related to per capita income and public health development.

![Figure 3](https://journalrip.com)
Limitations of the study
(A) Since the reviewed studies expressed the age of subjects as age range and the expressed time intervals overlapped with each other, we could not present the prevalence of UTI separately based on age groups. B) Lack of reporting the prevalence of symptoms of childhood UTIs such as fever and dysuria in the reviewed articles.

Acknowledgments
The authors wish to thank all the researchers whose studies were used in this meta-analysis. The authors would like to thank Abbas Moghimbeigi for guidance and editing of manuscript registration on the PROSPERO website.

Authors’ contribution
Conceptualization: TJ, DS, AA, SHA and MF.
Methodology: DS and AH.
Formal analysis: DS and MF.
Writing—original draft preparation: All authors.
